Key Points:

- Wave-ripple dimensions provide important information on past subaqueous environments
- Here, a clean-sand method is adapted for clay-sand mixtures by incorporating the effect of changes in the threshold of motion and dimensions
- Clay can result in a reduction in the range of past water-surface wavelengths and water depths, which is largest for coarse sand

18 **Abstract**

19 Wave ripples can provide valuable information on their formative hydrodynamic conditions in past
20 subaqueous environments by inverting dimension predictors. However, these inversions do not
21 usually take the mixed non-cohesive and cohesive nature of sediment beds into account. Recent
22 experiments involving sand–kaolinite mixtures have demonstrated that wave-ripple dimensions
23 and the threshold of motion are affected by bed clay content. Here, a clean-sand method to
24 determine wave climate based on orbital ripple wavelength has been adapted to include the effect
25 of clay and a consistent shear-stress threshold parameterisation. Based on present-day examples
26 with known wave conditions, the results show that the largest clay effect occurs for coarse sand
27 with median grain diameters over 0.45 mm. For a 7.4% volumetric clay concentration, the range
28 of possible water-surface wavelengths and water depths can be reduced significantly, by a factor
29 of three and four, respectively, compared to clean sand.

30 **Plain Language Summary**

31 In shallow water, ripples form on the seabed under water-surface waves due to friction. Knowledge
32 of this process allows preserved ripples to be used to infer past environmental conditions.
33 Traditionally, the method of inferring past environments from wave ripples has only involved sand,
34 despite mixtures of sand and sticky mud being more common in nature. Based on the results of
35 recent mixed sand–mud experiments, the effect of including small amounts of mud in the analysis
36 is shown to be an important modifying factor in determining past environments.

37 **1 Introduction**

38 Bed-surface structures in sediments and sedimentary rocks of past subaqueous
39 environments provide important information on flow hydraulics (e.g. Collinson & Mountney,
40 2019). These structures tend to be classified on the basis of the presence or absence of cohesion in
41 equivalent modern environments: (a) cohesive structures, associated with physical cohesion by
42 clay particles and biological cohesion by extracellular polymeric substances (e.g. biofilms,
43 Vignaga et al., 2013), where the bed is stabilised by cohesion between grains and sudden
44 catastrophic failure may occur under high bed shear stress, e.g. during storms; and (b) non-
45 cohesive bedforms (e.g. wave and current ripples: Wiberg & Harris, 1994; Baas, 1994), where
46 grains can move individually and tend to respond more rapidly and continuously to changes in
47 flow forcing (Perron et al., 2018). Examples of these types of bed-surface structure include roll-
48 ups (Cuadrado, 2020) and non-cohesive wave ripples (e.g. Allen, 1981). Davies (2016) argued that
49 the distinction between cohesive and non-cohesive sedimentary structures is artificial, as they
50 represent end members of a spectrum, and thus predictions based on one classification may result
51 in misinterpretations. This position is re-enforced by recent experiments that have shown how
52 sandy bedforms can be affected by small amounts of biological and physical cohesion (Malarkey
53 et al., 2015; Parsons et al., 2016; Wu et al., 2018; 2022). The consequence for wave ripples of
54 physical cohesion associated with kaolin clay in the bed has been detailed by Wu et al. (2024).
55 Building on the work of Allen (1981), Diem (1985) developed a clean-sand analytical method for
56 the prediction of paleowave climate based on the dimensional measurement of wave ripples in the
57 rock record (Aspler et al., 1994; Wetzel et al., 2003; Allen & Hoffman, 2005; Pochat & Van Den
58 Driessche, 2011, Lamb et al., 2012). Here, Diem’s (1985) approach is adapted for sand–clay
59 mixtures, using the synthesis proposed by Wu et al. (2024).

60 Diem's (1985) approach starts by determining the wave orbital diameter from the ripple
 61 wavelength, without requiring a specific wavelength predictor. Here, the formulation starts as
 62 Diem (1985) did, with linear wave theory and additional constraints based on threshold of motion
 63 and wave breaking. It will then return to the effect of clay on ripple-wavelength prediction and the
 64 threshold of motion. The importance of clay content is demonstrated with the use of present-day
 65 examples from the laboratory and field, where the wave conditions were known.

66 **2 Diem's (1985) method**

67 2.1 Linear wave theory

68 In linear wave theory, the dispersion relation and the wave-velocity amplitude, U_0 , are

$$\sigma^2 = gk \tanh kh, \quad U_0 = \pi d_0 / T, \quad (1a,b)$$

69 where $\sigma = 2\pi/T$, T is the wave period, g is the acceleration due to gravity ($= 9.81 \text{ m s}^{-2}$), $k = 2\pi/L$,
 70 L is the water-surface wavelength, h is the water depth, d_0 is the orbital diameter ($= H/\sinh kh$) and
 71 H is the wave height. The wave properties, characterised by eqs. (1a,b), are subject to two
 72 constraints:

73 2.1.1 Threshold of motion

74 U_t , the critical wave-velocity amplitude associated with the threshold of motion, is a function of
 75 d_0 and D_{50} , the median grain diameter. For sediment movement $U_0^2 > U_t^2$, which when combined
 76 with eqs. (1a,b) gives

$$x < \tanh kh, \quad (2)$$

77 where $x = L/L_{t\infty}$ and $L_{t\infty} = \frac{1}{2}\pi g(d_0/U_t)^2$ is the deep-water surface wavelength corresponding to the
 78 threshold of motion.

79 2.1.2 Wave breaking

80 According to Miche (1944), the wave-breaking criterion defines the maximum possible wave
 81 steepness as, $H/L \leq 0.142 \tanh kh$, which when combined with d_0 and $L_{t\infty}$ gives

$$x \geq A \cosh kh, \quad (3)$$

82 where $A = d_0/0.142L_{t\infty} = U_t^2/(0.071\pi g d_0)$. It will be shown below that $A < \frac{1}{2}$, so if $A = \frac{1}{2}(U_t/U_m)^2$,
 83 where $U_m = (0.0355\pi g d_0)^{1/2}$ is the maximum wave-velocity amplitude ($U_m > U_t$), then $U_t < U_0 \leq U_m$
 84 and from eq. (1b) $\pi d_0/U_m \leq T < \pi d_0/U_t$.

85 Eqs. (2) and (3) represent the range of possible conditions between threshold and wave breaking
 86 for the wave climate. The limits of these constraints can be found by combining eqs. (2) and (3)
 87 using the identity $1 - \tanh^2 kh = \text{sech}^2 kh$, such that the maximum and minimum in x satisfy the
 88 equation $x^4 - x^2 + A^2 = 0$, so that $x_{\max, \min}$ are

$$x_{\max, \min} = [\frac{1}{2} \pm \frac{1}{2}(1 - 4A^2)^{1/2}]^{1/2}, \quad (4)$$

89 where $A < \frac{1}{2}$, for there to be two distinct values. Here, x and kh are in the ranges $x_{\min} \leq x < x_{\max}$
 90 and $\arctan hx < kh \leq \text{arccosh}(x/A)$, respectively.

91 Figure 1 shows kh versus x for the limiting single-value case where $U_m^2 = U_t^2$ ($A = \frac{1}{2}$, $x = 2^{-1/2}$ and
 92 $kh = \arctan h 2^{-1/2} \sim 0.88$) from shallow water ($kh \ll 1$) to deep water ($kh \gg 1$). Figure 1 also shows

93 the $A = 1/4$ case ($U_m^2 = 2U_t^2$), corresponding to typical above-threshold wave conditions. In the
 94 latter case, the shaded region in Figure 1 shows the allowable values of x ($1/4 \cosh kh \leq x < \tanh kh$)
 95 and the dots mark $x_{\max, \min} = 1/2(2 \pm 3^{1/2})^{1/2}$ and $kh_{\max, \min} = \operatorname{arctanh}(x_{\max, \min})$. The breaking-wave curves
 96 ($x = A \cosh kh$) are concave downward and the threshold curve ($x = \tanh kh$) is concave upward.
 97 Notice for the breaking-wave curves, $x \rightarrow A$ for $kh \ll 1$ and A also controls the slope for larger kh .
 98 In dimensional terms, the water-surface wavelength, L , is therefore limited by the threshold scale
 99 ($L_{t\infty}$) and breaking-wave scale ($AL_{t\infty}$) according to $AL_{t\infty} < L \leq L_{t\infty}$. Then, from eqs. (2) and (3), the
 100 range of h can be expressed as a function of L as

$$(L/2\pi)\operatorname{arctanh}(L/L_{t\infty}) \leq h \leq (L/2\pi)\operatorname{arccosh}(L/AL_{t\infty}). \quad (5)$$

101 2.2 The ripple predictor

102 Diem's (1985) central assumption is that the orbital diameter can be expressed in terms of an
 103 equilibrium ripple wavelength, λ_e , as

$$\lambda_e = \alpha_0 d_0, \quad (6)$$

104 where $\alpha_0 = 0.65$, based on Miller and Komar's (1980) experiments, provided that $\lambda_e < 200$ mm (d_0
 105 = 308 mm). Above this limit, Diem (1985) proposed the use of Sleath's (1975) predictor. This
 106 arbitrary 200-mm limit represents the lower boundary of the suborbital and anorbital ranges, where
 107 the wavelength is dependent on both d_0 and D_{50} for suborbital ripples and only dependent on D_{50}
 108 for anorbital ripples. However, while a value of α_0 in the range $0.5 \leq \alpha_0 \leq 0.75$ in eq. (6) is widely
 109 accepted, there is little agreement in the literature on the precise nature of the orbital, suborbital,
 110 and anorbital limits. Wiberg and Harris (1994) defined orbital, suborbital and anorbital ripples by
 111 $d_0/D_{50} \leq 1754$, $1754 < d_0/D_{50} \leq 5587$ and $d_0/D_{50} > 5587$, respectively (Malarkey & Davies, 2003),
 112 whereas Mogridge et al. (1994) and Pedocchi and García (2009) argued the anorbital limit should
 113 have wave-period dependence. Provided that eq. (6) *does* hold, which is what will be assumed
 114 here, all quantities involving d_0 can now be expressed in terms of λ_e .

115 3 Adaptions to Diem's (1985) method

116 3.1 Threshold of motion parameterisation

117 Based on Soulsby's (1997) critical threshold of motion for clean sand, Appendix A derives an
 118 expression for U_t^2 , eq. (A2), such that U_t^2 , $L_{t\infty}$ and $AL_{t\infty}$ can be written

$$U_t^2 = B(gd_0^{0.52}D_{50}^{0.48}), \quad L_{t\infty} = \frac{\pi}{2B} \left(\frac{d_0^{1.48}}{D_{50}^{0.48}} \right), \quad AL_{t\infty} = \frac{d_0}{0.142}, \quad (7a,b,c)$$

119 where $B = 3.653(s-1)\theta_0$, s is the relative density of sediment in water (eq. A1), θ_0 is the critical
 120 skin friction Shields parameter (eq. A1), and $d_0 = \lambda_e/\alpha_0$ from eq. (6). Diem (1985) used Komar and
 121 Miller's (1973) mobility threshold prescription. Here, Soulsby's expression has been used, as it
 122 allows U_t^2 to be directly related to θ_0 and it avoids the need for two different functional forms, for
 123 $D_{50} < 0.5$ mm and $D_{50} \geq 0.5$ mm (eqs. (B1) and (B2)).

124 3.2 Inclusion of the effect of clay

125 Wu et al. (2024) showed that the ratio of wavelength to orbital diameter, α , which replaces α_0 in
 126 eq. (6), can be expressed as

$$\alpha = \alpha_0 \times \begin{cases} 1, & C_0 \leq C_{0m}, \\ 1 - 5.5(C_0 - C_{0m}), & C_0 > C_{0m}, \end{cases} \quad (8)$$

127 where α_0 is the clean-sand constant of proportionality (= 0.61), C_0 is the clay content in the bed
 128 and $C_{0m} = 7.4\%$ is the minimum value of C_0 where α can change from α_0 , and $\alpha = \frac{1}{2}\alpha_0$ for $C_0 =$
 129 16.3% . Whitehouse et al. (2000) showed that the threshold of motion is enhanced by the clay
 130 content according to

$$\theta_{0E} = \theta_0 B_\theta, \quad (9)$$

131 where θ_0 is the clean-sand threshold, $B_\theta = 1 + P_\theta C_0$ and P_θ is a constant that depends on the sediment
 132 properties. Based on their experiments, Wu et al. (2024) determined that $P_\theta = 6.3$ for $D_{50} = 0.143$
 133 mm and $P_\theta = 23$ for $0.45 \leq D_{50} \leq 0.5$ mm (between these two ranges, it will be assumed that P_θ
 134 can be linearly interpolated). Notice in eq. (9) that even small amounts of clay produce an
 135 enhancement which is strongly dependent on grain size.

136 Thus, the two main effects of including clay are that α is reduced and θ_{0E} is increased. Substituting
 137 eqs. (8) and (9), into eqs. (7a,b,c) gives U_t^2 , $L_{t\infty}$ and $AL_{t\infty}$ as

$$U_t^2 = B \left[\frac{B_\theta}{\alpha^{0.52}} \right] (g\lambda_e^{0.52} D_{50}^{0.48}), \quad L_{t\infty} = \frac{\pi}{2B[B_\theta \alpha^{1.48}]} \left(\frac{\lambda_e^{1.48}}{D_{50}^{0.48}} \right), \quad AL_{t\infty} = \frac{\lambda_e}{0.142[\alpha]}, \quad (10a,b,c)$$

138 where λ_e is the mixed clay–sand ripple wavelength and only the square-bracketed quantity in each
 139 expression depends on C_0 .

140 3.3 The method

141 The method begins with the determination of the ripple wavelength, λ_e , and bed-clay content, C_0 .
 142 Once these have been determined, the following calculations are undertaken:

143 (i) Use λ_e and C_0 in eqs. (10a,b,c), with α and B_θ given by eqs. (8) and (9), to determine U_t , $L_{t\infty}$ and
 144 $AL_{t\infty}$

145 (ii) Use A in eq. (4) to determine $x_{\max,\min}$, so that $x_{\min} \leq x \leq x_{\max}$

146 (iii) Use $L = L_{t\infty} x$ to determine the range of h based on eq. (5) and U_t and $U_m = (0.0355\pi g\lambda_e/\alpha)^{1/2}$ to
 147 determine the ranges of U_0 and T : $U_t < U_0 < U_m$ and $\pi\lambda_e/\alpha U_m < T < \pi\lambda_e/\alpha U_t$

148 4 Example cases

149 With specific examples from the rock record, Diem (1985) was able to show how local
 150 considerations and context could be used to further limit the theoretical ranges described in the
 151 previous section. Here, modern-day examples, where the wave properties are known, are used, so
 152 that attention can be focussed on the effect of clay on the theoretical ranges alone. The example
 153 cases correspond to clean, coarse-, medium- and fine-grained sand from the laboratory and field,
 154 and involve determining how wave conditions based on the measured ripples change if the clay
 155 content is varied in the range $0 \leq C_0 \leq 16.3\%$.

156 4.1 Wu et al. (2018), coarse-sand laboratory data

157 Wu et al. (2018) conducted a series of experiments involving a single-wave condition over a bed
 158 composed of well-sorted coarse sand, $D_{50} = 0.496$ mm ($\theta_0 = 0.032$), and varying clay content, $0 \leq$
 159 $C_0 \leq 7.4\%$. For the clean sand experiment ($C_0 = 0\%$), the wave conditions were given by $h = 0.6$

160 m, $H = 0.16$ m and $T = 2.49$ s ($L = 5.62$ m), corresponding to $d_0 = 0.223$ m. This experiment
161 produced ripples with a wavelength $\lambda_e = 278D_{50}$ (Wu et al., 2024). Figure 2a show the threshold
162 and wave-breaking scales, $L_{t\infty}$ and $AL_{t\infty}$, versus C_0 . $L_{t\infty}$, which is smallest at $C_0 = 7.4\%$, has a much
163 larger range than $AL_{t\infty}$, which is constant for $C_0 \leq 7.4\%$ and then doubles up to $C_0 = 16.3\%$. Figure
164 2d shows the corresponding $L-h$ phase space, based on eq. (5), for the clay contents depicted in
165 Figure 2a ($C_0 = 0, 7.4$ and 16.3%). Compared to the dimensionless $x-kh$ plot (Figure 1), the
166 threshold curves are still concave downwards, but more exaggerated, and the breaking-wave
167 curves are close to straight lines. The change in ranges is largely due to changes in $L_{t\infty}$. The
168 reduction in range between the largest and smallest (corresponding to $C_0 = 0\%$ and 7.4%) is by a
169 factor of 3 and 4 for the water-surface wavelength and water depth, respectively (Figure 2d).
170 Notice that the actual surface wavelength and water depth ($L = 5.62$ m, $h = 0.6$ m) are within all
171 three ranges. Figures 2a,d can be compared with Figures B1a,b to see the effect of using the Komar
172 and Miller (1973) clean-sand mobility description for the threshold. This shows $L_{t\infty}$ to be about
173 63% of its value in Figure 2a, because $B = 0.21(s-1) = 0.34$ as opposed to $3.653(s-1)\theta_0 = 0.19$.
174 Thus, using Diem's (1985) clean-sand mobility description underpredicts the range of water-
175 surface wavelengths and heights in an absolute sense. In a relative sense, the change in the ranges
176 of clay content is similar, because the powers of d_0 and D_{50} are similar (eq. (B2), for $D_{50} < 0.5$ mm,
177 and eq. (10a)), but this will not be the case for $D_{50} > 0.5$ mm. Also, the measured L and h are not
178 within the $C_0 = 7.4\%$ range (Figure B1b). As L and h are below the threshold curve, this would
179 imply that ripples of this size are relict for this clay content. This is inconsistent with the
180 experimental results, since Wu et al. (2024) showed no reduction in λ_e for $C_0 \leq 7.4\%$.

181 4.2 Doucette (2000), medium-sand field data

182 Doucette's (2000) field measurements were taken on a microtidal beach of Wambro Sound (run
183 1) where $h = 0.47$ m, $H = 0.2$ m and $T = 5.6$ s ($L = 11.9$ m), corresponding to $d_0 = 0.79$ m. The bed
184 was composed of medium sand, with $D_{50} = 0.22$ mm ($\theta_0 = 0.045$), and the measured ripples had a
185 wavelength of $\lambda_e = 250$ mm. Since $d_0/D_{50} = 3591$, the ripples were in the suborbital range (see
186 section 2.2), where the wavelength is dependent on both the orbital and grain diameters. Notice
187 this wavelength is above Diem's (1985) 200-mm limit. The supporting information demonstrates
188 that, whilst using Sleath's (1975) predictor for $C_0 = 0$ produces a difference, it is similar to the
189 other two example cases, which are below Diem's (1985) limit, and so is not considered
190 significant. From interpolation, P_θ in eq. (9) is determined to be 10. Figure 2b shows $L_{t\infty}$ and $AL_{t\infty}$
191 versus C_0 and Figure 2e shows the $L-h$ phase space, for $C_0 = 0, 7.4$ and 16.3% . These reveal similar
192 behaviour to that of the coarse-grained sand case, but less extreme: in Figure 2b, $L_{t\infty}$ is still at its
193 minimum at $C_0 = 7.4\%$ and $AL_{t\infty}$ shows the same enhancement as in Figure 2a. The reduction in
194 range between the largest and smallest ($C_0 = 0\%$ and 7.4%) is by a factor of 2 for both the water-
195 surface wavelength and water depth (Figure 2e). Again, the actual surface wavelength and water
196 depth ($L = 11.9$ m, $h = 0.47$ m) are within all three ranges.

197 4.3 Boyd et al. (1988), fine-sand field data

198 Boyd et al.'s (1988) field measurements were undertaken about 1 km from Martinique Beach on
199 the Atlantic coast of Nova Scotia during a period of relative calm (day 167, hour 9) where $h = 10$
200 m, $H = 0.5$ m and $T = 6.2$ s ($L = 50.7$ m), corresponding to $d_0 = 0.32$ m. The bed was composed of
201 well-sorted fine sand, with $D_{50} = 0.11$ mm ($\theta_0 = 0.076$), and the measured ripples had a wavelength
202 of $\lambda_e = 180$ mm. $d_0/D_{50} = 2873$ puts the ripples into the suborbital range. Assuming that P_θ in eq.
203 (9) is the same as for 0.143 mm ($P_\theta = 6.3$), Figure 2c shows $L_{t\infty}$ and $AL_{t\infty}$ versus C_0 and Figure 2f

204 shows the $L-h$ phase space, for $C_0 = 0, 7.4$ and 16.3% . $L_{t\infty}$ in Figure 2c is still at its minimum at
205 $C_0 = 7.4\%$, but, because of far weaker clay enhancement of the threshold for fine sands in eq. (9),
206 $L_{t\infty}$ is largest for $C_0 = 16.3\%$. In Figure 2f, the measured water-surface wavelength and water depth
207 ($L = 50.7$ m, $h = 10$ m) are below the threshold curve and outside the range for the $C_0 = 0$ and 7.4%
208 clay contents, and just above the threshold curve and within range for $C_0 = 16.3\%$, because, unlike
209 the previous cases, $C_0 = 16.3\%$ produces the largest $L_{t\infty}$. Since there was little clay at the field site,
210 the wave conditions were probably below threshold, implying that the observed ripples were relict.
211 This is supported by the fact that Boyd et al.'s (1988) previous observation at day 167, hour 3,
212 showed the same wavelength and no ripple migration. The reduction in range between the largest
213 and smallest ($C_0 = 16.3\%$ and 7.4%) is again by a factor of 2 for both the water-surface wavelength
214 and water depth (Figure 2f).

215 **5 Discussion**

216 The range of L shown in Figure 2 is largely controlled by $L_{t\infty}$, so it is of interest to determine how
217 the change in clay content affects $L_{t\infty}$, eq. (10b), compared to the original clean-sand Diem method
218 using Komar and Miller (1973), $L_{t\infty KM}$, eq. (B2) with $C_0 = 0\%$. The net effect is shown as a ratio
219 in Figure 3 for $C_0 = 0, 7.4$ and 16.3% and $0.1 \leq D_{50} \leq 0.8$ mm, for the approximate limits in the
220 range of λ_e/D_{50} of 250 and 1,000. There are two competing effects: the reduction because of clay
221 content (Figure 2) and the increase because of using Soulsby's (1997) threshold condition rather
222 than Komar and Miller's (1973). Figure 3 shows a discontinuity for clean sand at $D_{50} = 0.5$ mm as
223 a result of eq. (B2), leading to the largest difference ($L_{t\infty}$ is increased by up to 161% for $\lambda_e/D_{50} =$
224 250), which decreases with increasing λ_e/D_{50} (although Diem's (1985) method has rarely been
225 applied for $D_{50} > 0.5$ mm). Otherwise for $D_{50} \leq 0.19$ mm, $L_{t\infty}$ is reduced by up to 36%, and for
226 $0.19 < D_{50} \leq 0.5$ mm, $L_{t\infty}$ is increased by up to 64%. For $C_0 = 7.4\%$, $L_{t\infty}$ is consistently decreased
227 by between 35 and 56%, and for $C_0 = 16.3\%$, $L_{t\infty}$ varies only slightly (increased by up to 14%, for
228 $0.12 \leq D_{50} \leq 0.37$ mm, and otherwise reduced by up to 15%). The absence of a discontinuity in the
229 present formulation, compared to Diem's (1985) original formulation, is clearly preferable. Also,
230 the net effect of the clay on $L_{t\infty}$ will be stronger for smaller than for larger clay contents.

231 It is important to clarify how a representative clay content, C_0 , for the ripples should be determined.
232 In the modern environment this usually involves measuring C_0 below the active layer (below
233 trough level), as efficient winnowing often removes clay from the body of the ripples during
234 development (Wu et al., 2022). In the geological record, clay content in deposits should be based
235 on primary clay minerals and diagenetic alterations for which it can be established that the original
236 mineral was part of the primary clay fraction.

237 **6 Conclusions**

238 Preserved sedimentary bedforms provide important information for reconstructing past hydraulics
239 in subaqueous environments by inverting bedform predictors, but this is usually based exclusively
240 on non-cohesive sand. The present work incorporates the effects of sand-clay mixtures on
241 bedforms, using the experimental results of Wu et al. (2024) in the non-cohesive inversion method
242 of Diem (1985). Based on wave breaking and threshold of motion limitations, Diem's (1985)
243 approach results in ranges for wave conditions. Here we have shown that the inclusion of as little
244 as 7.4% clay in the most extreme case of coarse sand, $D_{50} \geq 0.45$ mm, reduces the possible ranges
245 of water-surface wavelengths and water depths by factors of 3 and 4, respectively. For fine sand,
246 the ranges are reduced by a factor of two. In short, not accounting for the modifying effect of clay

247 in ripple growth and equilibrium geometries, may lead to underestimating the prevailing flow
 248 conditions if clay is present.

249 **Appendix A: Determination of U_t^2 based on Soulsby (1997)**

250 According to Soulsby (1997), the Shields parameter for the critical threshold of motion of clean
 251 sand is

$$\theta_0 = \frac{0.3}{1+1.2D_*} + 0.055(1-e^{-0.02D_*}), \quad (\text{A1})$$

252 where $D_* = [(s-1)g/v^2]^{1/3}D_{50}$, $s = \rho_s/\rho$, ρ_s and ρ are the water and sediment densities and v is the
 253 kinematic viscosity ($\sim 1 \text{ mm}^2 \text{ s}^{-1}$). For waves, $\theta_0 = f_w U_t^2 / 2(s-1)gD_{50}$, where $f_w = 1.39(6d_0/D_{50})^{-0.52}$
 254 is the skin friction factor (Soulsby et al., 1993). Rearranging the θ_0 wave expression gives U_t^2 as

$$U_t^2 = B(gd_0^{0.52}D_{50}^{0.48}), \quad (\text{A2})$$

255 where $B = 6^{0.52}(s-1)\theta_0/0.695 = 3.653(s-1)\theta_0$. Eq. (A2) can be compared with eq. (B1).

256 **Appendix B: Diem's (1985) threshold of motion constraint**

257 Diem (1985) used the Komar & Miller (1973) expression for U_t^2 , namely

$$U_t^2 = (s-1)g \times \begin{cases} 0.21(d_0^{0.5}D_{50}^{0.5}), & D_{50} < 0.5 \text{ mm}, \\ 0.46\pi(d_0^{0.25}D_{50}^{0.75}), & D_{50} \geq 0.5 \text{ mm}, \end{cases} \quad (\text{B1})$$

258 such that with the inclusion of clay $L_{t\infty} = \pi g d_0^2 / 2B_\theta U_t^2$, $d_0 = \lambda_e/\alpha$ and B_θ and α are given by eqs. (8)
 259 and (9), giving $L_{t\infty}$ as

$$L_{t\infty} = \frac{\pi}{2(s-1)} \times \begin{cases} \frac{1}{0.21[B_\theta \alpha^{1.5}]} \left(\frac{\lambda_e^{1.5}}{D_{50}^{0.5}} \right), & D_{50} < 0.5 \text{ mm}, \\ \frac{1}{0.46\pi[B_\theta \alpha^{1.75}]} \left(\frac{\lambda_e^{1.75}}{D_{50}^{0.75}} \right), & D_{50} \geq 0.5 \text{ mm}, \end{cases} \quad (\text{B2})$$

260 and $AL_{t\infty}$ as $\lambda_e/0.142[\alpha]$ remains the same. Figure B1 shows the effect of this parameterisation of
 261 the threshold of motion for the first example case of Wu et al. (2018) depicted in Figures 2a,d.
 262 Unlike Figure 2d, the measured values of h and L are outside the range predicted for $C_0 = 7.4\%$.

263 **Acknowledgments**

264 The participation of JM, EMP, XW, RF, JHB and DRP was made possible thanks to funding by
 265 the European Research Council under the European Union's Horizon 2020 research and
 266 innovation program (grant no. 725955). Participation of RF was also supported by the Leverhulme
 267 Trust, Leverhulme Early Career Researcher Fellowship (grant ECF-2020-679).

268 **Open Research**

269 Eqs. (8) and (9) are from Wu et al. (2024), which has its own open-access policy.

362 **Figure 1** kh versus x (L/L_{∞}) for the limiting case of $A = 1/2$ and also $A = 1/4$. Dots correspond to $x =$
 363 $2^{-1/2}$ and $kh = \operatorname{arctanh} 2^{-1/2}$, for $A = 1/2$; $x_{\max, \min} = 1/2(2 \pm 3^{1/2})^{1/2}$ and $kh_{\max, \min} = \operatorname{arctanh}[x_{\max, \min}]$, for $A =$
 364 $1/4$, and shading represents allowable values of x and kh for $A = 1/4$ ($1/4 \cosh kh \leq x \leq \tanh kh$).

365 **Figure 2** (a,b,c) Threshold, $L_{t\infty}$, and wave-breaking, $AL_{t\infty}$, scales, eqs. (10b,c), versus C_0 and (d,e,f)
 366 $L-h$ phase space from eq. (5), showing the different ranges for $C_0 = 0, 7.4$ and 16.3% and the
 367 measured L and h . For (a,d) Wu et al. (2018), $\lambda_e = 278D_{50}$, $D_{50} = 0.496$ mm, $\theta_0 = 0.032$, $L = 5.62$
 368 m and $h = 0.6$ m; for (b,e) Doucette (2000), $\lambda_e = 250$ mm, $D_{50} = 0.22$ mm, $\theta_0 = 0.045$, $L = 11.9$ m
 369 and $h = 0.47$ m, and for (c,f) Boyd et al. (1988), $\lambda_e = 180$ mm, $D_{50} = 0.11$ mm, $\theta_0 = 0.076$, $L = 50.7$
 370 m and $h = 10$ m. Legend applies to d,e,f; colours in a,b,c are consistent with the legend.

371 **Figure 3** Relative size of $L_{t\infty}(C_0)$ from eq. (10b) normalised by the clean-sand $L_{t\infty}$ from eq. (B2),
 372 $L_{t\infty KM}$, for $C_0 = 0, 7.4$ and 16.3% . $\lambda_e/D_{50} = 250$ and 1000 , and the dots correspond to Wu et al.'s
 373 (2018) clean-sand experiment in Figure 2a.

374 **Figure B1** (a) Threshold, $L_{t\infty}$, and wave-breaking scales, $AL_{t\infty}$, eqs. (B2) and (10c), versus C_0 and
 375 (b) $L-h$ phase space from eq. (5) showing the different ranges for $C_0 = 0, 7.4$ and 16.3% and the
 376 measured h and L for Wu et al. (2018), $\lambda_e = 278D_{50}$, $D_{50} = 0.496$ mm, $h = 0.6$ m and $L = 5.62$ m.
