Table S.1. UAVSAR scenes used.

| Feature creation parameters | | |
|------------------------------|--|--|
| Parameter | Value | Description |
| Minimum incidence angle | 0.5 radians | Minimum incidence angle to mask in radians |
| Maximum incidence angle | Infinity | Maximum incidence angle to mask in radians |
| Offset filter dimensions | 3x3 px | Offset filter is simply a Gaussian smoothing filter applied to a center pixel a given offset away, used as input to classifier |
| Offset filter orientation | Parallel and anti-parallel to look angle | Direction relative to look angle |
| Offset filter gaussian width | 2 px | Determines effective radius of filter, used as classifier input |
| Guided filter | 5x5 px | Edge-preserving smoothing for classifier input |

| | | |
|--------------------------------------|--------|--|
| Standard deviation filter dimensions | 5x5 px | Texture metric for classifier input |
| Use raw image | True | Use the raw, unfiltered image as a feature for classifier input. |
| Classifier parameters | | |
| Parameter | Value | Description |
| Out-of-bag prediction error | 0.167 | Not a parameter, but a result |
| Number of trees | 40 | Number of decision trees |
| Minimum leaves per tree | 30 | Nodes per tree |

Table S.2 Land cover classification filter parameters and random forests classifier parameters.

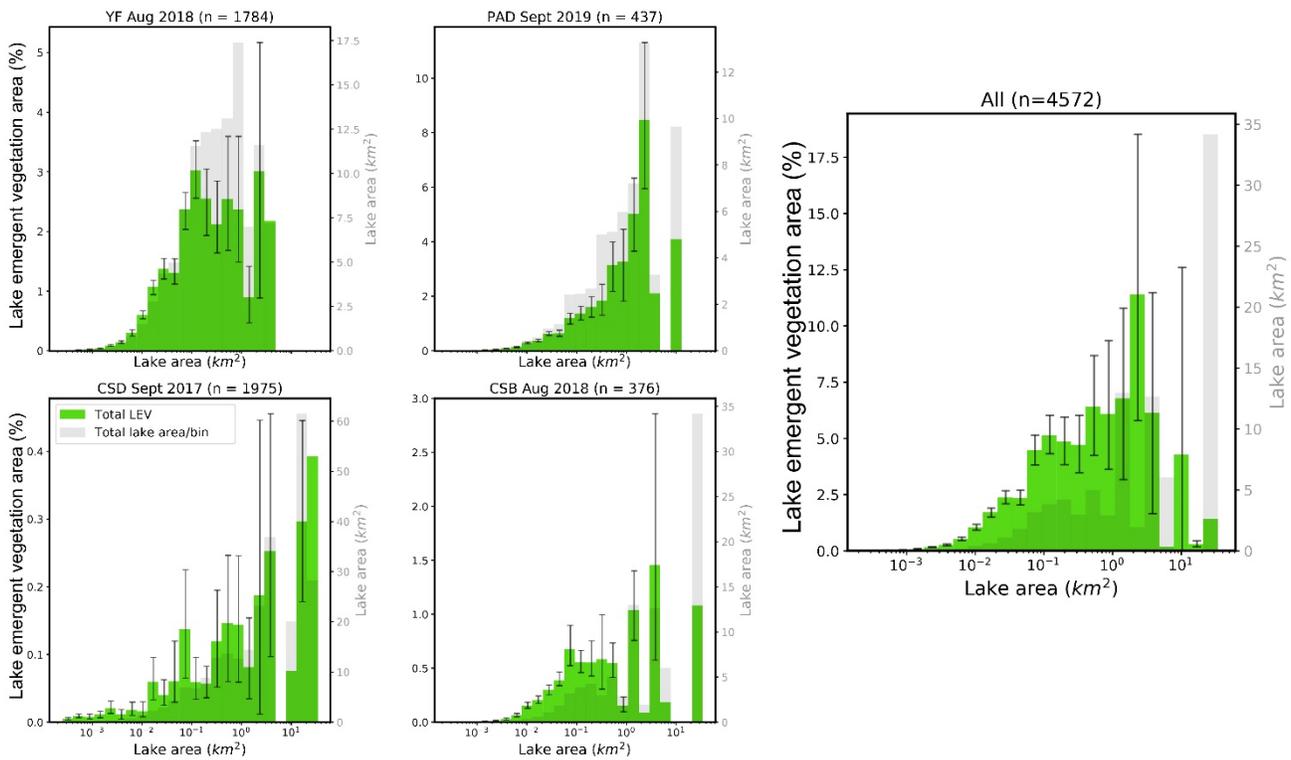

Figure S.2. Lake emergent vegetation (LEV) area summed by logarithmically-spaced lake area bins, in contrast with **Figure 4**, which uses bin means. Most LEV area comes from the largest size bins for each region. When combined (**right plot**), the trend still holds, although of the 10 lakes comprising the final four bins, all but one come from Canadian Shield lakes, so they are not showing a domain-wide trend. This situation, combined with the lesser macrophyte coverage in the Shield and correspondingly different y-axis scaling causes the outlier behaviour in the final four bins of the combined plot.

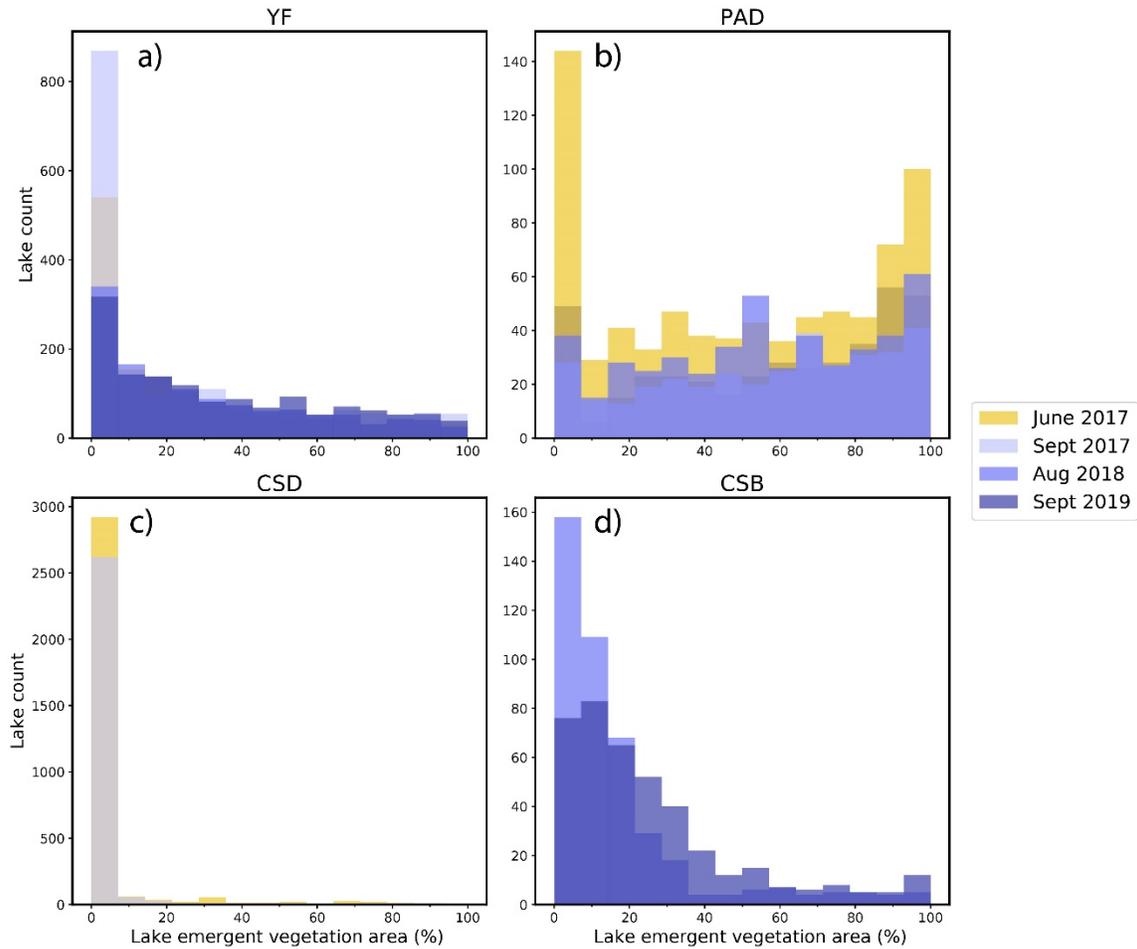

Figure S.3 Although the overall lake count changes across seasons and years as water bodies merge during high water seasons, the distributions of lake emergent vegetation (LEV) coverage remain similar. Histograms are made with 25 equally-spaced bins for each UAVSAR acquisition date for each region. Early summer dates (high water season) are plotted in gold and late summer in shades of purple, with intersections in shades of purple-grey. CSD was only acquired in June and September 2017 and CSB in August 2018 and September 2019.

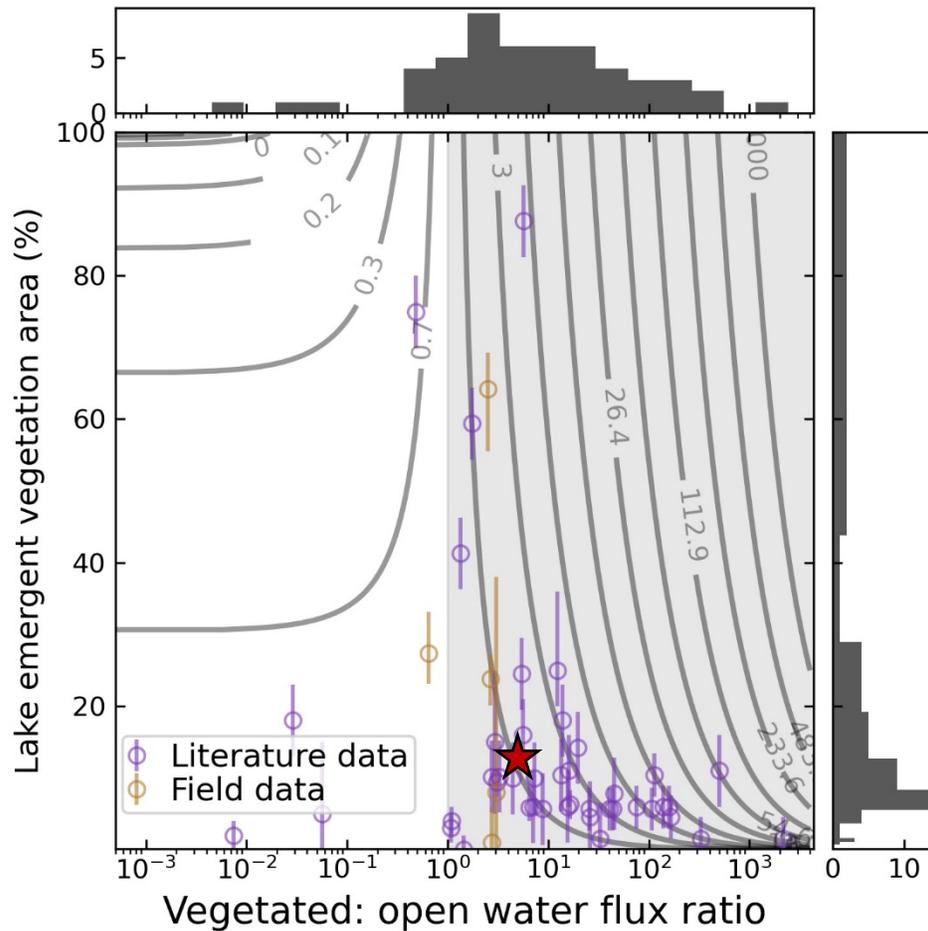

Figure S.4. Scatter plot of data from PAD and published literature showing the vegetated: open water methane flux ratio plotted against lake emergent vegetation (LEV) coverage as a percentage of each lake. The distributions of both variables are shown as histograms along the relevant axes. Vertical error bars show the temporal range in coverage for the field data (orange) and the estimated mapping uncertainty for the literature data (purple). Points falling in the shaded region come from lakes that would have higher calculated fluxes if their LEV zones are accounted for separately from open water. Contour lines show how much higher this calculated flux would be (I) and are logarithmically spaced to achieve uniform separation in a log-log space. Using the corrected median flux ratio (4.6) and area-weighted mean macrophyte coverage (16%) leads to fluxes 21% times greater (located at the red star). Note the logarithmically-scaled x-axis and linearly-scaled y-axis.

Figure S.6: Photos of emergent macrophyte (left) and open water (right) chamber flux collection.

Table S.3. See supplementary file “Literature_flux_data.csv” for a table showing collection dates and locations for field flux measurements at 15 lakes in the Peace-Athabasca Delta, July-August 2019. Methane fluxes are given in units of $\text{mgCH}_4/\text{m}^2/\text{day}$ for the type of lake zone considered (LEV = lake emergent vegetation, OW = open water, S = shallow, D = deep) and include attributes for confidence intervals or ranges, if given; flux pathway(s); emergent macrophyte delineation method uncertainty, and percentage; total macrophyte percentage, if applicable; and citation. The flux ratio is calculated based on the lake zone division of the paper (LEV versus OW or S versus D).

Additional data published on the Environmental Data Initiative (EDI, <https://doi.org/10.6073/pasta/1e0cadadd8024c8fab692ee21dc1f57>) contains a table showing collection dates and locations for field flux measurements at 15 lakes in the Peace-Athabasca Delta, July-August 2019. Fluxes are given in units of $\text{mol}/\text{m}^2/\text{day}$ for both methane and carbon dioxide and include attributes for location and vegetation type, if applicable, as well as a quality flag that indicates if the data were used.

| | | UAVSAR | | |
|----------|----------|--------|-------|--------------|
| | | Land | Lake | LEV |
| GLO-WABO | Not lake | 32.9% | 19.6% | 83.0% |
| | Lake | 67.1% | 80.4% | 17.0% |

| | | UAVSAR | | |
|-------------|----------|--------|-------|-------|
| | | Land | Lake | LEV |
| Hydro-Lakes | Not lake | 15.0% | 3.5% | 45.0% |
| | Lake | 85.0% | 96.5% | 55.0% |

Table S.4. Confusion matrices between two global lake datasets and our lake classification from UAVSAR, normalized by column totals. From the total area of lake emergent vegetation (LEV) considered in the analysis, these matrices show that only 17.0% (GLOWABO; Verpoorter et al. 2014) to 55.0% (HydroLakes; Messenger et al., 2016) coincides with global dataset lakes, which are commonly used to distinguish between lakes and wetlands for methane modelling. Therefore, we use the mean value of 0.36 as the scalar c that corrects for double-counting between our mapped lake emergent macrophytes and areas that are already considered (high-emitting) wetlands in global datasets.

| | HydroLakes | | Total | GLOWABO | | Total |
|------------|--------------|--------------|--------------|--------------|--------------|--------------|
| | Not Lake | Lake | | Not Lake | Lake | |
| Lake | 700206 | 19550038 | 20250244 | 4113557 | 16837558 | 20951115 |
| WG | 129790 | 163736 | 293526 | 301827 | 63198 | 365025 |
| WS | 5575 | 2148 | 7723 | 8778 | 577 | 9355 |
| WF | 93 | 4 | 97 | 104 | 1 | 105 |
| Wetland WG | 874 | 8195 | 9069 | 755 | 4285 | 5040 |
| Wetland WS | 7 | 107 | 114 | 5 | 8 | 13 |
| Wetland WF | 0 | 0 | 0 | 0 | 0 | 0 |
| Other | 483521 | 2737609 | 3221130 | 771296 | 1570154 | 2341450 |
| Total | 1320066 | 22461837 | 23781903 | 5196322 | 18475781 | 23672103 |
| WG/LEV | 95.8% | 98.7% | 97.4% | 97.1% | 99.1% | 97.5% |

Table S.5. More detailed confusion matrices between two global lake datasets and our lake classification from UAVSAR. Unlike **Table S.4**, lake emergent vegetation (LEV) is broken out into wet graminoid (WG), wet shrub (WS), and wet forest (WF) classes to facilitate comparing their relative proportions after comparing to the global datasets. As mentioned in **Section 2.3.8**, prior to the comparison to the global datasets, lakes from HydroLakes/GLOWABO or our classification were excluded if they didn't overlap at least partly with a lake in the comparison dataset. This step generally removed the smallest lakes and most of the WS and WF classes. The confusion matrix shows that regardless of global dataset or agreement with its lake classes, most of the remaining LEV is WG.

| | Region | Baker | Daring | PAD | YF | Late summer mean | Late summer area-weighted mean |
|-------------------------------------|------------------------------|--------|--------|--------|--------|------------------|--------------------------------|

| | LEV + WEV | 4.3 | 0.6 | 12.9 | 3.8 | 4.9 | 3.8 |

Table S.6. Comparison between UAVSAR land cover classification and the Boreal and Arctic Wetland and Lake Dataset (BAWLD, Olefeldt et al., 2021a, Olefeldt et al., 2021b). Relevant BAWLD classes are permafrost bogs (PEB), tundra wetlands (WTU),

marshes (MAR), bogs (BOG), fen (FEN), mid-sized peatland lakes (MPL), mid-sized yedoma lakes (MYL), mid-sized glacial lakes (MGL), small peatland lakes (SPL), small yedoma lakes (SYL), small glacial lakes (SGL), rivers (RIV), total lakes (LAK, defined as lentic open-water ecosystems), and total wetlands (WET). Since individual wetland classes are not equivalent between datasets, we suggest comparing total BAWLD MAR and FEN with total UAVSAR lake emergent vegetation (LEV) and wetland emergent vegetation (WEV) as roughly equivalent open water wetland classes. Study area-weighted mean open lake coverage shows remarkable agreement between the datasets (16.6% in both with variability based on study area), and the equivalent emergent vegetation and/or wetland classes are 24% greater in BAWLD (3.8% from UAVSAR, 4.7% from BAWLD). In summary, current methods show good agreement in detecting open water (including submerged vegetation) lakes, and poor agreement in detecting wetlands or total inundation, even when lake and wetland classes are mutually exclusive within each dataset.
